NON-WARRANTY—NOTE—We exercise great care in the selection of our stock but as there are so many contingencies to be encountered in growing plants from seed and in setting out plants that are dependent on weather and other conditions over which we have no control, that success in planting is not altogether dependent on the seed or plant. It being an established precedent of the Seed and Nursery Trade, we give no warranty, expressed or implied, as to description, quality, productiveness or any other matter of any seeds, bulbs, plants or trees we send out and we will not be responsible in any way for the crop. If the purchaser does not accept these terms the goods are to be returned at once. **HALLAWELL SEED CO.**

HOW TO GROW VEGETABLES

ARTICHOKE

One ounce will sow 200 feet of row, and produce about 500 plants. Six ounces will plant an acre. A deep rich sandy loam is best adapted for this plant. The seed should be sown thinly in drills 1½ inches deep and 1 foot apart. When large enough transplant to permanent rows 3 feet apart, allowing 2 feet between the plants. They reach maturity the second year, and in the northern states should be protected in winter by a covering of leaves or coarse manure. A bed will continue bearing for several years.

Jerusalem, or Tuberous-Rooted Artichoke. Entirely distinct, and grown exclusively for their large potato-like roots. The tubers are planted in February and March about 2 inches deep and 18 inches apart in rows 3 feet apart. The tubers are cooked as a vegetable or eaten raw as a salad. Extensively used for feeding hogs and rabbits.

ASPARAGUS

One ounce will sow 50 feet of row, and produce about 800 plants. Four to five pounds will plant an acre. Sow the seed early in spring in drills 12 to 14 inches apart, and when well started thin out to 3 inches apart. When one or two years old transplant into permanent beds, thoroughly trenched, 2 feet or more in depth. Set the plants in rows 2 feet apart, and not less than 18 inches apart in the row. Care should be taken that roots are well spread, and set at a depth of 6 inches below the level of the bed. Cover only 2 or 3 inches, and fill in gradually as the plants grow. Very little, if any, should be cut the first year after transplanting, but a fair crop can be cut the second year. Every fall after the tops have been cut down apply a dressing of coarse manure, and in the spring fork it in. An occasional top-dressing of salt at the rate of ½ pound per square yard is also beneficial, and keeps down the weeds.

ASPARAGUS ROOTS

A saving of one or two years is effected by planting roots. A bed 12 by 40 feet, requiring about 100 roots, should give a sufficient supply for an ordinary family. If planted in rows 3 feet apart and 2 feet between the plants, 7,200 roots will plant an acre.

BEANS

Beans should not be sown until April 15th, or until all danger from frost is over, and for a continuous supply should be planted every four weeks until August. A warm, well drained, sandy loam is best suited. Sow the bush varieties in rows 2 feet apart and 3 inches apart in the row. Plant the pole beans 4 feet apart in hills and set a pole firmly in each hill. Sow 5 or 6 beans in a hill. Cover the seeds from 1 to 2 inches deep. One pound of the bush varieties will sow 100 feet of row and 35 pounds will plant an acre. One pound of the pole varieties will plant 100 hills and 25 pounds will plant an acre.

LIMA BEANS

Limas are very sensitive to cold and overmoist ground and should not be planted until May, when the soil has warmed up. Stick the seed edgewise with the eye down into the soil, covering the seed 1 to 2 inches deep. See that the ground is moist so that the beans will not require any watering until the seeds have sprouted, otherwise they are apt to rot. Sow the bush varieties in rows 2 feet apart and 5 inches apart in the row. Plant the pole beans 4 feet apart in hills and set a pole firmly in each hill. Sow 5 or 6 beans in a hill. Plant in a rich, mellow soil and cultivate frequently. One pound of the bush varieties will sow 100 feet of row and 1 pound of the pole varieties will plant 75 hills.

BEETS FOR TABLE USE

One ounce will sow 50 feet of drill; 5 pounds will plant an acre, and will mature in 65 to 75 days. Rich deep soil, not too recently manured, is best for this crop; sow about 1 inch deep in drills 15 inches apart, and when well established thin the plants to 6 inches apart in the rows. Beets can be planted any time of the year.

MANGEL WURZEL AND SUGAR BEETS

Largely Grown for Feeding Stock

Five or six pounds will plant 1 acre, and will mature in about 150 days. The seed should be planted in rows 2 feet apart and thinned to 8 inches in the rows. To obtain the best results from this crop, use deep soil, well plowed; if the soil is thin a liberal application of a reliable chemical fertilizer is necessary.

BROCCOLI

Broccoli is a very late hardy Cauliflower. The culture is easy and the heads mature at a time when garden vegetables are scarce. By sowing the different kinds in open beds in July so that well grown plants can be had for transplanting during September, it is possible to secure a succession of fine white heads from January to April. The plants require abundant irrigation and make most of their growth during late fall. One ounce will produce 1,000 plants. Sow the seed $\frac{1}{2}$ inch deep and transplant to rows $2\frac{1}{2}$ feet apart and $1\frac{1}{2}$ feet apart in the row. Cultivate the same as cabbage.

BRUSSELS SPROUTS

One ounce will produce 1,000 plants and will mature in about 150 days. Sow as directed for cabbage, and set the plants in rows $2\frac{1}{2}$ feet apart and 2 feet apart in the rows. They require a long season of growth, but with suitable soil and liberal manuring an excellent crop of this vegetable can be secured. Cultivate the same way as cabbage.

CABBAGE

It is difficult to give definite cultural directions for cabbage, since it is possible to have good cabbage at all seasons of the year in some parts of the country. Seed may be planted almost any time of the year. However, there are three seasons preferable for sowing—in September for early spring cabbages, from January to April for summer and fall cabbages, and July to August for winter cabbages. Sow the seed $\frac{1}{2}$ inch deep and transplant the early varieties to rows 24 inches apart and 18 inches apart in the rows. They will mature in about 105 days. The late varieties mature in about 150 days and should be planted in rows 30 inches apart and 24 inches apart in the row. To prevent the heads from splitting open before they are ready to be harvested, the plants should be loosened a little at the root. Cabbages require plenty of moisture, but too much water causes them to rot very readily.

CAULIFLOWER

Culture same as cabbage. Soil must be rich and deep, and the plants liberally supplied with water in dry weather. As the flower heads appear, the large leaves should be broken down over them to protect them from the sun and rain. One ounce will produce 1,000 plants and will mature in about 150 days. Sow from June to January.

CELERY

Sow the seed $\frac{1}{8}$ inch deep in open ground as soon as fit to work in April, or for very early use in hot bed or cold frame. Pressing in the seed has often been found more satisfactory than covering. Cut the tops off once or twice before planting out, to make them stocky. When the plants are 5 or 6 inches high, transplant to rows 2 feet apart and set the plants 6 inches apart in rows. Water freely and shade from sun until established. Cultivate well, and when large enough blanch by earthing up or by partly shading the rows with boards. One ounce will produce 2,000 plants; will mature in about 6 months.

CARROTS

Best results are obtained when carrots are planted in a rich, deep, sandy loam, well pulverized and deeply cultivated. For an early crop sow in March and April in drills about 1 foot apart, thinning out to 4 inches in the row; sow for main crop in August and September. The large late varieties for field culture should be sown in drills 3 to $3\frac{1}{2}$ feet apart, so as to cultivate by horse. An important point in sowing carrots, as in all other seeds, is to tread the row firmly after sowing. One ounce will sow over 100 feet of drill; 3 to 4 pounds for 1 acre. For garden purposes sow any time.

CELERIAC OR TURNIP ROOTED CELERY

Sow seed same as celery, transplant into rows 2 feet apart and about 6 to 8 inches in the row. No earthing up is required for celeriac, as it is the roots which are the edible part of the vegetable. For winter use, pack in damp sand or earth in cellar, or cover with straw and earth outside.

CHERVIL

May be planted any time in the early spring. The leaves should be kept cut, and if not allowed to run to seed, will keep green for a long time. Is more finely curled than parsley, and makes an excellent plant for garnishing. One ounce will plant 100 feet of row. Sow seed $\frac{1}{2}$ inch deep.

CHICORY

Used as substitute for coffee when the roots are dried and ground. The roots are also used for cooking, and are very palatable. Sow the seed $\frac{1}{2}$ inch deep early in the spring, thin the young plants to 6 inches and keep well hoed. The plant spreads from the root and is perennial; will mature in 120 days. One ounce will sow 400 feet of row; 4 pounds will plant an acre.

COLLARDS

A plant bearing a large mass of leaves on the top of a stout stalk. It is a species of cabbage, and the flavor is the same. It bears leaves all through the winter, and is used especially in the South for cabbage greens. Young plants may be started in boxes in early spring, and then transplanted to $1\frac{1}{2}$ feet apart each way, hoe often. One ounce will plant 400 feet of row.

CORN SALAD or FETTICUS

A salad plant used as a substitute for lettuce in salads, or may be cooked like spinach for greens. It does well in winter and spring and matures in about 100 days. On rich soil the leaves grow quickly and are exceedingly tender.

Sow from August to November in drills $\frac{1}{2}$ inch deep and thin out to 6 inches apart. Tread it lightly to secure germination.

SWEET or SUGAR CORN

Corn is sensitive to frost and is liable to rot in cold or wet ground. Plant in April or May, or when the ground has become warm. It will mature in 80 to 100 days and can be planted until July, in hills 2 by 3 feet apart. Cover 8 or 10 seeds about 1 inch deep; thin out to 3 plants to a hill. Plant in a rich moist soil; hoe and cultivate frequently. One pound will plant 100 hills, and 15 pounds will plant an acre.

Field corn should be planted in hills 4 feet apart each way; use 10 pounds to the acre.

CUCUMBERS

One ounce will plant 100 hills; 3 pounds will plant 1 acre. Cucumbers succeed best in a rich, loamy soil and should be planted in May when the ground has warmed up. Plant the seed in slightly raised hills, 4 feet apart each way, place 6 or 8 seeds in each hill in a circle and cover with one inch of fine soil. After the plants are well started thin out to four. Cucumbers thrive well on well rotted compost and a shovelful of old manure should be placed 6 inches deep under each hill and firmly tramped down. Have the soil moist before planting so that no watering is required until the seeds have sprouted, otherwise they are apt to rot. After they commence to set fruit, water freely by sprinkling vines for about 10 minutes every other day or so. They mature in 120 days.

CRESS or PEPPER GRASS

Used as a salad, either alone or mixed with other greens; also used for garnishing. Sow thickly in shallow drills about 1 foot apart.

WATERCRESS

This is sown by the side of running water. It is altogether an aquatic plant and forms an early and wholesome spring salad.

DANDELION

One ounce will sow 200 feet of drill. It will mature in six months and should be sown in May and June in drills 18 inches apart and $\frac{1}{2}$ inch deep. The leaves are best for salads when blanched, by partly shading the rows with boards.

EGG PLANT

One ounce will produce 1,000 plants. A strong, uniform heat is required to germinate the seeds, and a thoroughly pulverized well-enriched, warm soil is necessary to perfect the fruit. Sow the seed from January to March $\frac{1}{4}$ inch deep and transplant when all danger from frost is over $2\frac{1}{2}$ feet apart each way, and when about a foot high, support the plants by drawing the earth up around them. Egg plants mature in 150 to 160 days.

ENDIVE

One ounce will sow 100 feet of drill. Sow the seed $\frac{1}{2}$ inch deep in any ordinary soil from June to October in drills $1\frac{1}{2}$ feet apart, covering lightly. When the plants are about 2 inches high, thin to about 8 inches in the row. When the plants have attained full size, gather up the leaves, tying together at the tips. This excludes the air from the inner leaves, which in the course of three or four weeks will become blanched.

GARLIC

Prepare ground same as for onions, plant the cloves (separate portions of the bulbs) in drills, 8 inches apart and 4 inches apart in the row, covering 2 inches deep. When the leaves turn yellow take up the bulbs, dry in shade and lay them up in a dry loft as you would onions.

KALE or BORECOLE

This plant is useful for furnishing a large supply of greens for boiling during the early fall, winter, and spring months. Sow the seed thinly in drills, transplanting to rows 2 feet apart when of sufficient size. Sow as directed for cabbage. One ounce will produce 1,000 plants; 2 to 3 ounces will plant an acre.

KOHL RABI—TURNIP ROOTED CABBAGE

One ounce will produce 1,000 plants. Sow the seed $\frac{1}{2}$ inch deep in rows 18 inches apart, afterwards thinning to 8 or 10 inches. The bulb is the edible part and when cooked tastes very much like turnip. Kohl Rabi will mature in 120 days and may be sown from January to May and from July to October.

LEEK

Sow from January to April, in drills 1 foot apart and $\frac{1}{2}$ inch deep. When the plants are 6 to 8 inches high transplant in a deep, rich soil, in rows 12 inches apart and 4 inches in the rows, as deep as possible, so that the neck may be covered and blanched; draw the earth to them as they grow. The seed may also be sown in July or August for good plants in the fall and winter. One ounce will plant 200 feet of row; 4 pounds will plant an acre.

LETTUCE

Lettuce seed should be covered very lightly to secure germination. When well started transplant to rows 18 inches apart and 6 inches apart in the row. It may be planted throughout the season in most localities, and will mature in 65 to 90 days according to the variety and season of planting. One ounce will sow 200 feet of row; 4 pounds will plant an acre.

MUSHROOM SPAWN

Ten pounds will spawn about 10 feet square. Mushrooms can be grown in any dark room or cellar where the temperature can be kept at from 50 to 70 degrees. From some old pasture procure good, rich soil, and to every bushel of this soil add 2 bushels of fresh horse manure. Of this well-mixed compound prepare a bed, say 4 feet wide. Put down a thin layer and pound it down hard, and go on until you have a bed 12 or 18 inches thick. As soon as the temperature of the bed falls from 75 to 50 degrees, the spawn may be inserted in pieces about the size of a walnut, about 2 inches deep and 6 inches apart. Cover with loamy soil about 2 inches deep and beat it down evenly and firmly. Finish off with a covering of clean hay, about a foot thick, and the work is done. If the temperature is right, in 6 or 8 weeks you may expect mushrooms. The beds will continue bearing from 20 to 30 days.

After the first crop is gathered spread over the bed an inch of fresh soil, moisten with warm water, and cover with hay as before. The main conditions in mushroom growing are proper and uniform temperature and very rich soil.

MUSKMELON

One ounce will plant 80 hills; 3 pounds will plant an acre. A light, warm, rich soil is essential for this crop. When all danger from frost is over, plant the seed in slightly raised hills 4 feet apart each way, placing 6 to 8 seeds in each hill in a circle and covering with one inch of fine soil. Place a shovelful of old manure about 6 inches under each hill and tamp down firmly. Have the soil moist before planting so that no watering is required until the seeds have sprouted, otherwise they are apt to rot. After all danger of destruction by bugs is over, thin out to 3 plants to a hill; when about 1 foot long pinch off the tips to make them branch. This strengthens the growth of the vines and makes the fruit mature early. Muskmelons mature in 120 to 140 days.

WATERMELON

One ounce will plant 35 hills; 3 to 4 pounds will plant an acre. The culture of watermelons differs from that of muskmelons mainly in that the hills should be wider apart, from 8 to 10 feet, according to the variety grown. An effort should be made to secure good strong vines early in the season, and this can best be done by taking care that the hills are large, mellow, and well drained, with the manure placed so that they will not dry out quickly under hot suns. Plant the seeds thickly when danger of frost is over and thin the plants to four of the strongest in each hill. All possible protection from insects should be given the young plants and their growth may be still further hastened by frequent application of liquid manure. They mature in 120 to 140 days. As a protection from insects, netting is frequently used.

OKRA or GUMBO

This vegetable is extensively grown for its green pods, which are used in soups, stews, etc., and matures in about 75 days. Sow the seed thickly in rich ground about the middle of May, or when the ground has become warm, until June, in drills 3 feet apart, 1 inch deep; thin to 18 inches apart in the drills.

ONION

The best onions are grown on low, sandy, or mucky lands, with natural moisture, and plenty of it. Higher lands can be used if irrigated, provided the land is rich and very well worked before planting the seed. Onions do not follow a hay or grain crop to good advantage, since the soil lacks nitrogen and humus. A piece of land contemplated for onions should be planted to beans, peas, or some other vegetable crop one or two years.

On high lands the seed should be sown in December or early in January, while on low lands any time from February 1st to March 10th will do, depending on the condition of the weather. Sow in rows from 12 to 16 inches apart, using 4 to 5 pounds of seed for an acre. In irrigating onions, it is important that the land never be allowed to get dry, for a check in the growth will either force the plant to run to seed or will make stiff necks. In the home garden plant early in rows one foot apart and thin to 4 inches apart in the row. Sow the seed $\frac{1}{2}$ inch deep, using one ounce to 200 feet of row. Onions mature in about 150 days.

PARSLEY

Used for garnishing and seasoning soups, meats, etc. Succeeds best in a mellow, rich soil. Sow thickly at any season in rows 1 foot apart and $\frac{1}{4}$ inch deep; thin out plants to stand 6 inches apart in the rows. The seed is slow of germination, taking from three to four weeks to make its appearance, and often failing to come up in dry weather. To assist its coming up quicker, soak the seed a few hours in warm water, or sprout in damp earth, and sow when it swells or bursts. One ounce will sow 400 feet of row; 3 pounds will plant an acre.

GARDEN PEAS

A light, moderately rich soil is best for peas. For early peas sow in the fall, and for successive crops plant until July. Plant the dwarf varieties in single or double rows 18 inches apart and about 2 inches apart in the row. The tall sorts should be planted in rows 3 feet apart. Sow the seed 2 to 3 inches deep, and in dry weather soak the seeds for 5 or 6 hours in water before planting. One pound will sow 100 feet of row, and 80 to 150 pounds will plant an acre. Peas mature in 8 to 12 weeks.

PEPPER

Peppers are indispensable as a seasoning for soups and meats. The large varieties are mainly used for this purpose and for pickling. The mild, sweet varieties, like Sweet Mountain and Bell, are used for Mangoes, while the small-fruited sorts are the best for sauces. They mature in 140 to 150 days. Sow $\frac{1}{4}$ inch deep in hotbeds in February or March, and, when danger from frost is over, transplant in rows 2 feet apart and 18 inches in row, in good rich ground.

PARSNIPS

One ounce will sow 200 feet of drill; 3 pounds will plant an acre. This crop requires a very rich soil. Sow from February to September in drills 18 inches apart and $\frac{1}{2}$ inch deep, and thin to 8 inches to the row. Besides being desirable as a vegetable they are valuable for feeding stock, and mature in 125 days.

PUMPKIN

One ounce will plant 20 hills; 5 pounds will plant an acre. Plant after all danger of frost is over, until June, in hills 6 to 8 feet apart each way, covering seed 1 to 2 inches deep, allowing 3 strong plants to a hill. In other respects they are cultivated as melons and cucumbers; keep separate from melons and cucumbers, as they are liable to mix. Pumpkins mature in about 100 days.

POTATOES

The soil best suited to the potato is a rich, sandy loam, but it seems to thrive in almost any soil or climate. The potato, being a gross feeder, requires a liberal application of manure or bone meal; if stable manure is to be used, it should be well rotted, and not allowed to come in contact with the tubers. Use at the rate of 500 to 600 pounds to the acre. Plant as early in the spring as the ground can be thoroughly worked, in rows 3 feet apart and 15 inches in the rows for early potatoes and 18 inches apart for late ones; covering in light warm soil about 6 inches, and in heavy soil about 4 inches deep; draw the earth to the plants as they advance in growth. Eight pounds will plant 100 feet of row. Cut the tubers up in good-sized pieces each containing not less than two or three eyes; they are sometimes cut up a day before planting so as to allow the cut portions to become calloused.

RADISH

Radishes thrive best in a light, rich, mellow soil, and to bring out their mild qualities they must make a quick and tender growth. Sow early in spring and well into summer for succession, in well-manured, deeply dug and finely raked soil; if not well stimulated into a rapid growth, they become fibrous and tough; sow in drills 10 inches apart and $\frac{1}{2}$ inch deep, and thin to 2 inches in the rows. Sow at intervals of two or three weeks until September for a succession. They mature in 25 to 40 days. Sow winter varieties in July and August; like the turnip, they make the best growth in autumn, and must be taken out before severe frost, and stored away in a cool cellar in sand, where they will keep tender and crisp all winter; before using put in cold water, which adds to the freshness. One ounce will sow 100 feet of row, 10 pounds will plant an acre.

RHUBARB

Sow in drills $\frac{1}{2}$ inch deep; thin out to 6 inches apart. In fall, trench a piece of ground and manure it well and then transplant the young plants into it 3 feet apart each way. Cover with leaves or litter the first winter, and a dressing of manure should be given every fall. It is better to plant strong roots, as they will produce next spring. One ounce will sow 200 feet of row.

SALSIFY or OYSTER PLANT

One ounce will sow 100 feet of row; 8 pounds will plant an acre. The soil should be rich and well worked to a depth of at least 18 inches. Sow in drills 15 inches apart, covering the seeds with fine soil $\frac{1}{2}$ inch in depth. When the plants are strong enough, thin them out to about 3 inches apart. The seed may be sown from February to September and will mature in 150 days.

SPINACH

One ounce will sow 100 feet of drill; 8 pounds for an acre. Select very rich, well-drained soil, sow in drills 1 foot apart and $\frac{1}{2}$ inch deep. For spring and summer use make the first sowing early in spring and continue at intervals for two or three weeks, until the middle of June; sow in August and September for winter and early spring use; will mature in about 45 days.

SQUASH

Squash should be planted in a warm, rich soil, after the weather has become settled and warm, about the beginning of May or June. Plant in well-manured hills, in the same manner as cucumbers or melons—the bush varieties 3 or 4 feet apart each way, and the running kinds from 6 to 8 feet. 8 to 10 seeds should be sown, 1 to 2 inches deep, in each hill, thinning out after they have attained their rough leaves and danger from bugs is over, leaving 3 or 4 of the strongest plants to a hill. The soil should be moist before planting so that no watering is required until the seeds have sprouted, otherwise they may fail to germinate. An occasional feeding of liquid manure will repay in size of fruits. One ounce will plant 35 hills of the bush varieties. Four to six pounds is required to an acre. One ounce will plant 15 hills of the Winter varieties, and 3 to 4 pounds is required to an acre. Summer sorts mature in 65 days and the winter sorts in 150 days.

TOMATO

For early plants sow in hotbeds early in March or April, in drills 5 inches apart and $\frac{1}{4}$ inch deep; when the plants are about 2 inches high, transplant into another hotbed 4 inches apart each way; plant out in the open ground early in May, or as soon as danger from frost is over, 4 feet apart each way in hills, which should have a shovelful of well-rotted manure mixed with the soil. Water freely at time of transplanting, but after the plants are well established water sparingly and at the roots only, as spraying the vines and overwatering causes the blossoms to drop off; when the first fruit is set, pinch off the ends of the branches to obtain early fruit. Sufficient plants for a small garden can be grown in a shallow box by placing it in a sunny window in a warm room. For late use sow in a sheltered border in May, and set out the plants in July; the green fruit can be picked off before frost and ripened under glass. By training the vines on trellises or tying to stakes, the fruit will ripen better and be of finer quality. The fruit matures in 150 days.

TURNIP

For early use, sow in January and February, in drills from 12 to 15 inches apart, covering the seed $\frac{1}{2}$ inch deep; thin out to 3 or 4 inches in the rows. For succession, continue to sow every two weeks until June; for fall and winter crop, sow in July and August. The Ruta Bagas are grown for feeding stock and are also excellent for the table. Take up the roots in November, or before severe frosts; cut off tops within an inch of the crown, store in cool cellar or pit. One ounce will sow 200 feet of row; 3 to 4 pounds will plant an acre; they mature in 60 to 70 days.

LAWN GRASSES

The ground should first be deeply spaded, adding commercial fertilizer or pulverized sheep manure, and should then be leveled to the proper grade. A good plan is to let it lay for several weeks and water thoroughly. This will give a chance for many of the weed seeds to sprout and they can be hoed off as they come up. After the weeds have been removed, rake the surface smoothly and sow the seed broadcast at the rate of one pound to 150 square feet, except where noted.

After the seed has been sown, it should be covered with about one-quarter inch of good mulch, such as Holland Peat. This is very essential as it is necessary that the surface be kept continually moist giving the seed an opportunity to germinate. Burlap is sometimes used in place of a mulch on steep banks or slopes as it keeps the surface moist and also prevents the seed from washing out. Remove burlap as soon as the seed germinates. Watering a newly sown lawn should be done very carefully with a fine, gentle spray and as often as is necessary to keep the surface moist at all times of the day, until the seed has germinated. When the grass is well up, and before cutting, it will be necessary to weed it, as even with the best of care there are bound to be some weeds produced from seeds which have been lying dormant in the ground or blown in from vacant lots, etc. This should be done carefully, pulling out all weeds by the roots. After the first cutting it should be fertilized and in order to maintain a deep velvety green turf a dressing should be applied at least three times a year.

Write for prices on larger quantities; these prices fluctuate and are not guaranteed. We prepay charges anywhere within the fourth zone on pound and ten pound lots of seeds.

Seasons to Sow Flower Seeds in Central California

This list enables one to tell at a glance when the various flower seeds may be sown. As some perennials will bloom the same season if sown early in the year, we have stated the latest time in Spring that they may be sown for this purpose. Several varieties of hardy annuals if sown in the Fall will come into bloom earlier than if sown in the Spring, even if the plants do not make much progress during the cold weather. Tender and half hardy annuals, if sown early, should be started in a warm, sheltered position and transplanted when the cold weather is over.

How to Raise Flowers Successfully from Seed

Tender, or Greenhouse, means the plant will not stand the least frost. All such must be planted out late in Spring (May) or in a greenhouse.

Half Hardy means the plant will stand any light frost, but needs protection against very cold weather. These should be planted out in the Spring (March and April), not in the Fall.

Hardy means the plant will stand considerable frost, or practically all we have on the Pacific Coast. These may be planted in the Fall or in the Spring (October to May). If sown in the Fall they will come into bloom earlier than if sown in Spring, even if the plants do not make much progress during the cold weather.

Annuals are plants that bloom the first year from seed, and the plant dies after one season. Tender annuals must be sown in Spring (February to June), and hardy annuals may be sown either in Fall or Spring (October to May).

Biennials are plants that bloom the second year from seed, and the plant dies after the second year. In California many of these will bloom the first year if sown early. Sow under the same condition as perennials.

Perennials are plants that bloom the second year from seed, and the plant lives and blooms during successive years. If sown in early Spring (February to March), many perennials will bloom the first year from seed. Perennials are best sown in the Summer and early Fall (June to October) for next year's flowers.

Cultural Directions—It is better in most instances, except hardy annuals, to start the seed in shallow boxes which should be about 4 inches in depth, using very sandy soil with leaf mold so that it will not bake, and provide for

drainage by boring some holes in the bottom of the box. Set the boxes in a warm sheltered place, but protect from direct sunlight, as the seed is liable to be scorched up. When the plants have made the fourth leaf they should be pricked out, reset in another box or preferably in paper pots and when well started they should be transplanted into the garden. If the seed is to be sown directly in the garden, it should be done after the soil is well worked and fertilized. A slight depression should be made with a stick, the seed sown, and then covered with sharp sand about twice the depth of the diameter of the seed. The sand will prevent the crusting over of the soil after watering.

When up, the plants must be thinned from 2 to 12 inches, depending on the variety, otherwise they will be weak and spindling. Always keep the weeds out.

A common mistake in sowing flowers, as well as other seeds, is covering too deep. As a general rule, cover only to the depth of the thickness of the seeds; or, with medium-sized seeds, like Balsams, Zinnias, etc., a quarter of an inch or less is the proper depth. Such fine seeds as Portulacas, Nicotiana, etc., need only to be pressed into the soil with a piece of board or the palm of the hand. Always press the earth down firmly after sowing all flower seeds, else there is danger of their drying up before the roots can get firm hold of the soil. Seeds of the hardier annuals may be sown where they are to grow; but as a rule, it is preferable to transplant, as the plants are generally stronger and stand the drought better. During very dry weather, and when the seedlings are first set out, they should be watered frequently. Provide some support for all such annuals as require it.

The weeds should be kept down and the ground loosened often, so that the plants will receive the full benefit of the rains and dews, which they will not if the ground is allowed to become hard and baked. Water often.

CLASSIFICATION OF FLOWERS

To enable one to tell at a glance what flowers are suitable for any position, we have classified all the different flowers of which we sell seed, into the following classes.

Where any variety is suitable for two uses, we have entered it under both lists.

Perennials are separated from Annuals, and Biennials are classed with the Perennials. Plants which do well in a shady location we have indicated by (s) after the name, and those that will do well in a partially shaded location are indicated by (ps).

One of the most attractive novelties. The plants are sturdy and strong, throwing up long flower stalks, making wonderful cut flowers. Some of the flowers have twisted petals and some have quilled petals; all have a cushion center of tiny quills of a contrasting color which makes the flower look as if it were covered with snowflakes. The blue flowers are dotted with a paler blue and some with white, and the rose with a lighter shade of pink or white. Their delicate beauty is hard to describe.

Nasturtium

For ease of culture, brilliancy of coloring and duration of bloom, nothing excels the Nasturtium.

Sow the seed where it is to remain late in the Spring after danger of frost is over.

It is seldom necessary to thin the young plants, as they will bear standing close together.

Nasturtiums prefer dry, rather rocky soil, such as we usually call "poor" soil, and bear their flowers in such locations in greater profusion than in a rich garden, where they run too much to leaves. This adds to their value for planting over many unsightly places. Do not water too much.

Hallawell's Quality Pansies

Pansies thrive best in a partially shaded location and in a loose soil, well enriched with decayed manure, which should be well dug into the soil. Seed should be sown in the Fall for early Spring blooming and early in the year until May for good flowers later in the Spring and Summer. The seed should be sown in boxes, covering them not more than four times their diameter and firming the soil well above them. Do not allow the seed to dry out. The plants must be transplanted twice in order to get the largest flowers; once from the seed box to a sheltered bed and again to the open ground. For best results, you must start a good strain. The finest Pansies are, as a rule, shy seeders, which accounts for the difference in price of the various mixtures offered.

Work the soil at least 18 inches deep, 2 feet is better, with plenty of rotten stable manure. Cow manure is the best; use some lime and crushed bone. Tamp the soil down firmly; never plant in loose soil. Take the hose and water down to the base. Let stand a few days until moderately moist. NEVER PUT THE SEED IN TOO WET SOIL. Rake off the surface nice and smooth, make rows and drop seed not over two inches deep, and two inches apart. Rake off again. DO NOT WATER UNTIL ALL THE SEED IS UP, AT LEAST HALF AN INCH OUT OF THE SOIL. (Nine-tenths of the failures are caused by watering too soon). Thin out to at least six inches apart and train on wire netting or strings when plants are five or six inches high. Applications of liquid manure during flowering period will add to the length of stems and size of blossoms.

THE ROSE

December, January, February and March are the best months for planting but should the season be favorable you can still plant during the early part of April. The plants sent out during these months are what we call dormant two-year-old budded plants. Roses give best results when planted in a fairly sunny location and in good heavy sediment soil to which may be added some old manure or bone meal, but never use fresh manure. When planting straighten out all roots and as the dirt is filled in see that it is well packed around them; this keeps out the air and encourages a new growth of rootlets. Be sure that the Rose is planted so that the point where it is budded shall be just below the surface.

Pruning

This should be done during the months of December, January and February; at that time the bushes are in a dormant condition. Cut just above a prominent but dormant bud that is pointing outward.

The Tea Varieties (T.) require to be more severely pruned than any other sort. Cut back to about 6 or 7 inches from the old wood each year; keep the center of the plant open and thin out all the weak wood, leaving about 5 or 6 shoots, according to the size of the plant.

Hybrid Teas (H. T.) should have almost as much pruning done as the Teas.

Hybrid Perpetuals (H. P.)—First cut out any dead or weak wood, keeping the center of the plant open, then cut the remaining shoots down to sound, healthy wood to within 6 or 12 inches of the base; this hard pruning keeps the plants compact and promotes new life for future years. After the first year they require little pruning except to cut out dead wood.

Austrian and Hybrid Briars (H. B.) require to be cut back fairly hard when planted out but afterwards need no pruning except to cut out dead wood.

Polyantha or Baby Roses (P.) should be but little pruned; merely cut out dead wood and keep the center of the plant from getting too crowded.

Single (S.) require little (if any) pruning when established, but will be the better for being cut back when planted.

Climbers. These are not usually pruned as their duties are to cover certain objects. They should, however, be periodically thinned out.

GLADIOLUS

The bulbs should be planted about 4 inches deep and 7 or 8 inches apart. Any good garden soil will make strong plants and good bloom, but a light application of any well decayed manure or good commercial fertilizer applied on the top of the ground after the plants are several inches high will aid in producing larger blooms. Keep the ground moist until the flower spikes begin to appear, then water freely. The bulbs should be taken up in the Fall, after the leaves have become yellow, and then stored in a cool, dry place, free from frost. From December to April are the months to plant Gladiolus.

FRUIT TREES AND SMALL FRUITS

SPECIAL NOTICE TO PURCHASERS

While we aim to have all our fruit trees true to name, and hold ourselves ready, on proper proof, to replace, free of charge, all stock that may prove untrue to label, or to refund amount originally paid by the customer, it is mutually understood and agreed between the purchaser and ourselves that our guarantee of genuineness shall not make us liable for any sum greater than that originally paid us for such stock as may prove untrue.

PLANTING AND PRUNING FRUIT TREES

PLANTING—Successful planters always dig good large holes for the roots. A little extra labor at this time will be amply repaid in the more rapid growth of the tree, and should the ground be at all heavy or sandy, add some old well-decayed manure. After the tree is set in the hole properly, commence to throw in the soil gently, and see that it is well pulverized, and work all in around the roots well. After the hole is half filled up, press down gently with the foot; then fill in the remainder, also going through the same process, leaving the last spadeful or two untrdden. Never, especially in soils that are apt to run together, or adobe, try to plant when the ground is wet. Wait until the ground dries; otherwise your trees will not grow so well.

Planting can be done from December to March, according to the season, but orders should be placed early with us, so as to obtain desired selections.

Frequent cultivating is necessary, as there is no better way of keeping the moisture near the surface.

PRUNING—All deciduous fruit trees should be pruned back severely after planting, usually $2\frac{1}{2}$ or 3 feet from the ground, according to the size of the tree, leaving a few side branches where necessary, which are cut back to a few inches from the main stem. Heading back promotes a vigorous new growth and a stocky tree, provides shade which protects the trunk from sunburn and the fruit being nearer the ground is more easily picked. When these trees have been planted one year, cut back at least half of the preceding summer's growth. Thus a framework is established for the tree.

Apples

The first Winter after planting the branches should be cut back at least one-half and thinned out so as not to leave more than four branches for the framework. The second Winter not more than two laterals should be allowed to remain on the branches whose growth should again be shortened very severely. With the head now practically formed the grower must shape the tree in accordance with its development by shortening the laterals where necessary and thinning out surplus shoots. It is not desirable to shorten in Apples as is done with the Apricot and Peach.

The third season two shoots should be allowed to start from the branches of the year before and they in turn should have their growth shortened in two-thirds. CITRUS FRUITS

Great care should be taken not to allow the ball of earth around the roots to dry out before planting. When planting do not break the ball of earth and leave the burlap around the earth, as this soon rots. The trees should be set from one to two inches deeper than in the nursery. Leave a basin around the tree and fill this with water. When the earth is dry enough to break up fine, cultivate carefully and irrigate every ten days or two weeks, until the trees begin to grow; after that irrigation is a matter of weather conditions, but never allow the trees to suffer for water. Citrus trees being evergreen can be planted at all seasons of the year although the months of March, April, May and June are considered the most favorable.

To cultivate the Strawberry for family use we recommend planting in beds 4 feet wide, with an alley 2 feet wide between the beds. These beds will accommodate 3 rows of plants, which may stand 15 inches apart each way, and the outside row 9 inches from the alley. The beds can be kept clean easier and the fruit gathered without setting feet upon them. The ground should be well prepared by digging at least 10 or 12 inches deep, and be enriched with well-rotted manure, ground bone, or any other good fertilizer. In order to obtain large, highly flavored fruit, pinch off the runners as fast as they appear and this will cause the plants to stock out. The earlier they are planted in the season the better crop you will have the first season.

After the new canes have grown 5 to 6 feet, prune off the tips of each cane to force out the side branches, provided you intend to stake or trellis. If you intend to let the plants stand alone, pinch off the tips when canes are 2 to 4 feet high. A good top dressing of well-rotted manure should be applied as soon as the patch is cleaned up.
